Lecture 5: Processing across rows Managing and Manipulating Data Using R Introduction

#### Logistics

#### Required reading for next week:

- ▶ Grolemund and Wickham 5.6 5.7 (grouped summaries and mutates)
- Xie, Allaire, and Grolemund 4.1 (R Markdown, ioslides presentations) LINK HERE and 4.3 (R Markdown, Beamer presentations) LINK HERE. Why?:
  - Lectures for this class are beamer\_presentation output type.
  - ioslides\_presentation are the most basic presentation output format for RMarkdown, so learning about ioslides will help you understand beamer

### What we will do today

- 1. Introduction
- 2. Introduce group\_by() and summarize()
  - 2.1 group\_by
  - 2.2 summarize()
- 3. Combining group\_by() and summarize()
  - 3.1 summarize() and Counts
  - 3.2 summarize() and means
  - 3.3 summarize() and logical vectors, part II
- 4. Summarize multiple columns
- 5. Attach aggregate measures to your data frame

### Libraries we will use today

"Load" the package we will use today (output omitted)

you must run this code chunk

library(tidyverse)

If package not yet installed, then must install before you load. Install in "console" rather than .Rmd file

- Generic syntax: install.packages("package\_name")
- Install "tidyverse": install.packages("tidyverse")

Note: when we load package, name of package is not in quotes; but when we install package, name of package is in quotes:

- install.packages("tidyverse")
- library(tidyverse)

### Data we will use today

Data on off-campus recruiting events by public universities

- Object df\_event
  - One observation per university, recruiting event

```
rm(list = ls()) # remove all objects

#load dataset with one obs per recruiting event
load(url("https://github.com/ozanj/rclass/raw/master/data/recruiting/recruit_ev
#load("../../data/recruiting/recruit_event_allvars.Rdata")
```

## Processing across variables vs. processing across observations

#### Visits by UC Berkeley to public high schools

```
\# # A tibble: 5 x 6
#>
     school id
                  state tot stu pub fr lunch pct fr lunch med inc
     <chr>
                  <chr>>
                              <dbl>
                                        <dbl>
                                                     <dbl>
                                                             <dbl>
#>
#> 1 340882002126 NJ
                               1846
                                           29
                                                    0.0157 178732
#> 2 340147000250 NJ
                               1044
                                                    0.0479 62288
                                           50
#> 3 340561003796 N.I.
                               1505
                                          298
                                                    0.198 100684.
#> 4 340165005124 N.I.
                               1900
                                           43
                                                    0.0226 160476.
#> 5 341341003182 NJ
                               1519
                                          130
                                                    0.0856 144346
```

So far, we have focused on "processing across variables"

- Performing calculations across columns (i.e., vars), typically within a row (i.e., observation)
- Example: percent free-reduced lunch (above)

Processing across obs (focus of today's lecture)

- Performing calculations across rows (i.e., obs), often within a column (i.e., variable)
- Example: Average household income of visited high schools, by state

### Why processing across observations

#### Note

in today's lecture, I'll use the terms "observations" and "rows" interchangeably

#### Creation of analysis datasets often requires calculations across obs

#### Examples:

- You have a dataset with one observation per student-term and want to create a variable of credits attempted per term
- You have a dataset with one observation per student-term and want to create a variable of GPA for the semester or cumulative GPA for all semesters
- Number of off-campus recruiting events university makes to each state
- Average household income at visited versus non-visited high schools

#### Creating graphs and tables of descripive stats usually require calculations across obs

Example: Want to create a graph that shows number of recruiting events by event "type" (e.g., public HS, private HS) for each university

- Start with df\_event dataset that has one obervation per university, recruiting event
- Create new data frame object that has one observation per university and event type and has variable for number of events
  - this variable calculated by counting number of rows in each combination of university and event type
- This new data frame object is the input for creating desired graph

Introduce group\_by() and summarize()

## Strategy for teaching processing across obs

In tidyverse the group\_by() and summarize() functions are the primary means of performing calculations across observations

- Usually, processing across observations requires using group\_by() and summarize() together
- group\_by() typically not very useful by itself
- summarize() [with or without group\_by()] can be helpful for creating summary statistics that are the inputs for tables or graphs you create

#### How we'll teach:

- ▶ introduce group\_by() and summarize() separately
  - poal: you understand what each function does
- then we'll combine them

group\_by

## group\_by()

**Description**: "group\_by() takes an existing data frame and converts it into a grouped data frame where operations are performed"by group". ungroup() removes grouping."

- part of dplyr package within tidyverse; not part of Base R
- works best with pipes %>% and summarize() function [described below]

Basic syntax: group\_by(.data, ...)

- .data argument refers to name of data frame
- argument refers to names of "group\_by" variables, separated by commas
  - Can "group by" one or many variables
  - ► Typically, "group\_by" variables are character, factor, or integer variables

Possible "group by" variables in df\_event data:

university name/id; event type (e.g., public HS, private HS); state

**Example**: in df\_event , create frequency count of event\_type [output omitted]

```
names(df_event)
#without group_by()
df_event %>% count(event_type)
df_event %>% count(instnm)
#group_by() university
df_event %>% group_by(instnm) %>% count(event_type)
```

### group by()

By itself group\_by() doesn't do much; it just prints data

```
▶ Below, group df_event data by university, event type, and event state
#print object
df event
#group by (without pipes)
group_by(df_event, univ_id, event_type, event_state)
#group by (with pipes)
df_event %>% group_by(univ_id, event_type, event_state)
df_event %>% group_by(univ_id, event_type, event_state) %>% glimpse()
```

But once an object is grouped, all subsequent functions are run separately "by group"

recall that count() counts number of observations by group

```
# count number of observations in group, ungrouped data
df event %>% count()
#group by and then count obs
df_event %>% group_by(univ_id) %>% count()
df_event %>% group_by(univ_id) %>% count() %>% glimpse()
df event %>% group by(univ id, event type) %>% count()
df_event %% group_by(univ_id, event_type) %>% count() %>% glimpse()
df_event %>% group_by(univ_id, event_type, event_state) %>% count()
df_event %>% group_by(univ_id, event_type, event_state) %>% count() %>% glimpse
```

## Grouping not retained unless you assign it

Below, we'll use class() function to show whether data frame is grouped

- will talk more about class() next week, but for now, just think of it as a function that provides information about an object
- similar to typeof(), but class() provides different info about object

#### Grouping is not retained unless you assign it

```
class(df_event)
#> [1] "tbl_df" "tbl" "data.frame"
df_event_grp <- df_event %>% group_by(univ_id, event_type, event_state) # using
class(df_event_grp)
#> [1] "grouped_df" "tbl_df" "tbl" "data.frame"

Use ungroup(object) to un-group grouped data

class(df_event_grp)
#> [1] "grouped_df" "tbl_df" "tbl" "data.frame"

df_event_grp <- ungroup(df_event_grp)

class(df_event_grp)
#> [1] "tbl_df" "tbl" "data.frame"

rm(df_event_grp)
```

# group\_by() student exercise

- 1. Group by "instnm" and get a frequency count.
- ▶ How many rows and columns do you have? What do the number of rows mean?
- Now group by "instnm" and "event\_type" and get a frequency count.
   How many rows and columns do you have? What do the number of rows mean?
- Bonus: In the same code chunk, group by "instnm" and "event\_type", but this
  time filter for observations where "med\_inc" is greater than 75000 and get a
  frequency count.

## group\_by() student exercise solutions

- 1. Group by "instnm" and get a frequency count.
  - ▶ How many rows and columns do you have? What do the number of rows mean?

```
df_event %>%
 group_by(instnm) %>%
 count()
#> # A tibble: 16 x 2
#>
   instnm
                   n
\#> < chr> < int>
#> 1 Arkansas 994
#> 2 Bama
                4258
#> 3 Cinci
                679
   4 CU Boulder
                1439
#>
#> 5 Kansas
                1014
#> 6 NC State
                640
#> 7 Pitt
                1225
#> 8 Rutgers 1135
#> 9 S Illinois
                549
#> 10 Stony Brook
               730
#> 11 UC Berkeley 879
#> 12 UC Truine
               539
#> 13 UGA
                827
                908
#> 14 UM Amherst
#> 15 UNL
                1397
#> 16 USCC
                1467
```

## group\_by() student exercise solutions

2. Now group by "instnm" and "event\_type" and get a frequency count.
How many rows and columns do you have? What do the number of rows mean?

```
df event %>%
 group_by(instnm, event_type) %>%
 count()
#> # A tibble: 80 x 3
#> instnm event type
#> <chr> <chr>
                     \langle int \rangle
                       32
#> 1 Arkansas 2yr college
#> 2 Arkansas 4yr college
                       14
#> 3 Arkansas other
                      112
   4 Arkansas private hs 222
#>
#>
   5 Arkansas public hs 614
#>
  6 Bama 2yr college 127
                       158
#> 7 Bama 4yr college
#> 8 Bama other
                      608
#> 10 Bama public hs
                       2402
#> # ... with 70 more rows
```

## group\_by() student exercise solutions

Bonus: Group by "instnm" and "event\_type", but this time filter for observations where "med\_inc" is greater than 75000 and get a frequency count.

```
df event %>%
 group_by(instnm, event_type) %>%
 filter(med inc > 75000) %>%
 count()
#> # A tibble: 80 x 3
#> instnm event type
#> <chr> <chr>
                      \langle int \rangle
#> 1 Arkansas 2yr college
#> 2 Arkansas 4yr college 3
#> 3 Arkansas other
                        30
#> 4 Arkansas private hs 99
#> 5 Arkansas public hs 303
#> 6 Bama 2yr college 21
#> 7 Bama 4yr college 42
#> 8 Bama other 249
#> 9 Bama private hs 477
#> 10 Bama public hs
                        1478
#> # ... with 70 more rows
```

summarize()

```
summarize() function
```

**Description**: summarize() calculates across rows; then collapses into single row

- summarize() create scalar vars summarizing variables of existing data frame
- if you first group data frame using group\_by(), summarize() creates summary vars separately for each group, returning object with one row per group
- if data frame not grouped, summarize() will result in one row.

#### Syntax: summarize(.data, ...)

- .data: a data frame; omit if using summarize() after pipe %>%
- Name-value pairs of summary functions separated by commas
  - "name" will be the name of new variable you will create
  - "value" should be expression that returns a single value like min(x), n()
  - variable names do not need to be placed within quotes

## Value (what summarize() returns/creates)

Object of same class as .data.; object will have one obs per "by group"

#### Useful functions (i.e., "helper functions")

- ➤ Standalone functions called within summarize(), e.g., mean(), n()
- e.g., count function n() takes no arguments; returns number of rows in group

#### **Example**: Count total number of events (output omitted)

```
summarize(df_event, num_events=n()) # without pipes
df_event %>% summarize(num_events=n()) # using pipes
```

## Investigate objects created by summarize()

#### Example: Count total number of events

```
df_event %>% summarize(num_events=n())
df_event %>% summarize(num_events=n()) %>% str()
```

#### Example: What is max value of med\_inc across all events

```
df_event %>% summarize(max_inc=max(med_inc, na.rm = TRUE))
df_event %>% summarize(max_inc=max(med_inc, na.rm = TRUE)) %>% str()
```

#### Example: Count total number of events AND max value of median income

#### Takeaways

- by default, objects created by summarize() are data frames that contain variables created within summarize() and one observation [per "by group"]
- most "helper" functions (e.g., max(), mean() have option na.rm to keep/remove missing obs before performing calculations)
  - na.rm = FALSE (default); don't remove NAs prior to calculation
     if any obs missing, then result of calculation is NA
  - na.rm = TRUE (default); remove NAs prior to calculation

## Retaining objects created by summarize()

Object created by summarize() not retained unless you assign it

```
event_temp <- df_event %>% summarize(num_events=n(),
   mean_inc=mean(med_inc, na.rm = TRUE))

event_temp
#> # A tibble: 1 x 2
#> num_events mean_inc
#> <int> <dbl>
#> 1 18680 89089.
rm(event_temp)
```

## Using [] operator to filter observations within summarize

Imagine we want to calculate avg. income, separately for in-state vs. out-of-state visits

```
first, let's use filter() to make sure we can identify in-state vs. out-of-state
#in state
df_event %>% filter(event_state == instst) %>% count() %>% as_vector()
#> n
#> 5425
#out state
df_event %>% filter(event_state != instst) %>% count() %>% as_vector()
#> n
#> 13255
```

calculate mean income for: all events; in-state events; out-of-state events

```
df_event %>%
    summarize(avg_inc = mean(med_inc, na.rm = TRUE), # all events
    avg_inc_inst = mean(med_inc[event_state == instst], na.rm = TRUE), # in-sta
    avg_inc_outst = mean(med_inc[event_state != instst], na.rm = TRUE) # out-st
)

#> # A tibble: 1 x 3

#> avg_inc_avg_inc_inst avg_inc_outst

#> <dbl> <dbl> <dbl> <dbl>
#> 1 89089. 71589. 96162.
```

## Using summarize() to create descriptive statistics table

Often helpful to use summarize() to calculate summary statistics that are the basis for a table of descriptive statistics

Task: create a table of descriptive statistics about variable med\_inc

want these measures: number of non-missing obs; mean; standard deviation

```
df_event %>% mutate(non_miss_inc = is.na(med_inc)==0) %>%
    summarize(
    n = sum(non_miss_inc, na.rm = TRUE), #SAMPLE SIZE all
    avg_inc = mean(med_inc, na.rm = TRUE), # MEAN
    std_inc = sd(med_inc, na.rm = TRUE), # STANDARD DEVIATION all events
)
```

Task: same as above but separate measures for: all events; in-state; out-of-state

```
df_event %>% mutate(non_miss_inc = is.na(med_inc)==0) %>%
    summarize(
    n = sum(non_miss_inc, na.rm = TRUE), #SAMPLE SIZE
    n_inst = sum(non_miss_inc[event_state == instst], na.rm = TRUE),
    n_outst = sum(non_miss_inc[event_state != instst], na.rm = TRUE),
    avg_inc = mean(med_inc, na.rm = TRUE), # MEAN
    avg_inc_inst = mean(med_inc[event_state == instst], na.rm = TRUE),
    avg_inc_outst = mean(med_inc[event_state != instst], na.rm = TRUE),
    std_inc = sd(med_inc, na.rm = TRUE), # STANDARD DEVIATION
    std_inc_inst = sd(med_inc[event_state == instst], na.rm = TRUE),
    std_inc_outst = sd(med_inc[event_state != instst], na.rm = TRUE)
)
```

## summarize() student exercise

- 1. What is the min value of med\_inc across all events?
  - ► Hint: Use min()
- 2. What is the mean value of fr\_lunch across all events?
  - ► Hint: Use mean()

## summarize() student exercise

1. What is min value of med\_inc across all events?

### summarize() student exercise

2. What is the mean value of fr\_lunch across all events?

Hint: Use mean()

df\_event %>%

summarize(mean\_fr\_lunch = mean(fr\_lunch, na.rm = TRUE))

#> # A tibble: 1 x 1

#> mean\_fr\_lunch

#> <dbl>
#> 1 475.

Combining group\_by() and summarize()

summarize() on ungrouped vs. grouped data:

- By itself, summarize() performs calculations across all rows of data frame then collapses the data frame to a single row
- When data frame is grouped, summarize() performs calculations across rows within a group and then collapses to a single row for each group

**Example**: Count the number of events for each university

remember: df\_event has one observation per university, recruiting event

```
df_event %>% summarize(num_events=n())
df_event %>% group_by(instnm) %>% summarize(num_events=n())
```

Investigate the object created above

```
df_event %>% group_by(instnm) %>% summarize(num_events=n()) %>% str()
```

Or we could retain object for later use

```
event_by_univ <- df_event %>% group_by(instnm) %>% summarize(num_events=n())
str(event_by_univ)
event_by_univ # print
rm(event_by_univ)
```

coord flip() + facet wrap(~ instnm)

#### Task

Count number of recruiting events by institution and event\_type df event %>% group by(instnm, event type) %>% summarize(num events=n()) #investigate object created df\_event ">" group\_by(instnm, event\_type) ">" summarize(num\_events=n()) ">" str Note that data frame object created by group\_by() and summarize() can be input to graph #bar chart of number of events, all universities combined df\_event %>% group\_by(instnm, event\_type) %>% summarize(num\_events=n()) %>% ggplot(aes(x=event\_type, y=num\_events)) + # plot ylab("Number of events") + xlab("Event type") +geom\_col() #bar chart of number of events, separete chart for each university df\_event %>% group\_by(instnm, event\_type) %>% summarize(num events=n()) %>% ggplot(aes(x=event\_type, y=num\_events)) + # plot ylab("Number of events") + xlab("Event type") + geom\_col() +

 $\textbf{Task.} \ \ Count \ number \ of \ recruiting \ events \ by \ institution, \ event\_type, \ and \ whether \ event \ is \ in- \ or \ out-of-state \ (var= \ event\_inst \ )$ 

Note: in group\_by() , the optional drop argument controls whether empty groups dropped. default is drop = TRUE

Make a graph, showing in/out state as fill color of bar

```
df_event %% group_by(instnm, event_type, event_inst) %%
summarize(num_events=n()) %>%
    ggplot(aes(x=event_type, y=num_events, fill = event_inst)) + # plot
    ylab("Number of events") + xlab("Event type") + geom_col() +
    coord_flip() + facet_wrap(~ instnm)
```

#### Task

▶ By university, event type, event\_inst count the number of events and calculate the avg. pct white in the zip-code

```
df_event %>% group_by(instnm, event_type, event_inst) %>%
    summarize(num_events=n(),
        mean_pct_white=mean(pct_white_zip, na.rm = TRUE)
)

#investigate object you created

df_event %>% group_by(instnm, event_type, event_inst) %>%
    summarize(num_events=n(),
        mean_pct_white=mean(pct_white_zip, na.rm = TRUE)
) %>% glimpse()
```

```
Recruiting events by UC Berkeley

df_event %>% filter(univ_id == 110635) %>%

group_by(event_type) %>% summarize(num_events=n())

Let's create a dataset of recruiting events at UC Berkeley

event_berk <- df_event %>% filter(univ_id == 110635)

event_berk %>% count(event_type)
```

summarize() and Counts

### summarize() : Counts

```
The count function n() takes no arguments and returns the size of the current group event_berk %>% group_by(event_type, event_inst) %>% summarize(num_events=n())

Because counts are so important, dplyr package includes separate count() function that can be called outside summarize() function event_berk %>% group_by(event_type, event_inst) %>% count()

event_berk %>% group_by(event_type, event_inst) %>% summarize(num_events=n()) # same same
```

## summarize(): count with logical vectors and sum()

Logical vectors have values TRUE and FALSE.

▶ When used with numeric functions, TRUE converted to 1 and FALSE to 0.

```
sum() is a numeric function that returns the sum of values
sum(c(5,10))
sum(c(TRUE,TRUE,FALSE,FALSE))

is.na() returns TRUE if value is NA and otherwise returns FALSE
is.na(c(5,NA,4,NA))
#> [1] FALSE TRUE FALSE TRUE
sum(is.na(c(5,NA,4,NA,5)))
#> [1] 2
sum(!is.na(c(5,NA,4,NA,5)))
#> [1] 3
```

Application: How many missing/non-missing obs in variable [very important]

```
event_berk %>% group_by(event_type) %>%
  summarize(
   n_events = n(),
   n_miss_inc = sum(is.na(med_inc)),
   n_nonmiss_inc = sum(!is.na(med_inc)),
   n_nonmiss_fr_lunch = sum(!is.na(fr_lunch))
)
```

Use one code chunk for this exercise. You could tackle this a step at a time and run the entire code chunk when you have answered all parts of this question. Create your own variable names.

- Using the event\_berk object, filter observations where event\_state is VA and group by event\_type.
  - 1.1 Using the summarize function to create a variable that represents the count for each event\_type.
  - 1.2 Create a variable that represents the sum of missing obs for med\_inc.
  - 1.3 create a variable that represents the sum of non-missing obs for med inc.
  - 1.4 Bonus: Arrange variable you created representing the count of each event\_type in descending order.

- - 1. Using the event\_berk object filter observations where event\_state is VA and group by event type.
    - 1.1 Using the summarize function, create a variable that represents the count for each event\_type .
    - 1.2 Now get the sum of missing obs for med inc .
    - 1.3 Now get the sum of non-missing obs for med inc.

```
event_berk %>%
  filter(event state == "VA") %>%
  group_by(event_type) %>%
  summarize(
   n = n(),
    n miss inc = sum(is.na(med inc)).
    n nonmiss inc = sum(!is.na(med inc))) %>%
  arrange(desc(n_events))
#> # A tibble: 3 x 4

summarize() and means

### summarize(): means

The mean() function within summarize() calculates means, separately for each group

```
event_berk %>% group_by(event_inst, event_type) %>% summarize(
 n events=n().
 mean inc=mean(med inc, na.rm = TRUE),
 mean_pct_white=mean(pct_white_zip, na.rm = TRUE))
#> # A tibble: 10 x 5
#> event_inst event_type n_events mean_inc mean_pct_white
#> <chr> <chr>
                      < i.n.t.>
                                 <d.b 1.>
                                              <d.b1.>
#> 1 In-State 2yr college 111 78486.
                                              40.1
#> 2 In-State 4yr college
                            14 131691.
                                            58.0
#> 3 In-State other
                            49 75040. 37.6
#> 4 In-State private hs
                            35 95229.
                                            48.4
#> 5 In-State public hs 259 87097.
                                             39.6
#> 6 Out-State 2yr college
                             1 153070.
                                              89.7
                             4 76913. 65.8
#> 7 Out-State 4yr college
#> 8 Out-State other
                            89 69004 . 56.5
#> 9 Out-State private hs 134 87654.
                                              64.3
#> 10 Out-State public hs
                           183 103603.
                                              62.0
```

## summarize() : means and na.rm argument

Default behavior of "aggregation functions" (e.g., summarize())

if input has any missing values ( NA ), than output will be missing.

Many functions have argument na.rm (means "remove NAs")

- na.rm = FALSE [the default for mean() ]
  - Do not remove missing values from input before calculating

    Therefore, missing values in input will cause output to be missing
- na.rm = TRUE
  - ▶ Remove missing values from input before calculating
  - Therefore, missing values in input will not cause output to be missing

```
#na.rm = FALSE; the default setting
event_berk %>% group_by(event_inst, event_type) %>% summarize(
 n events=n(),
 n_miss_inc = sum(is.na(med_inc)),
 mean_inc=mean(med_inc, na.rm = FALSE),
 n miss frlunch = sum(is.na(fr lunch)),
 mean_fr_lunch=mean(fr_lunch, na.rm = FALSE))
\#na.rm = TRUE
event berk %>% group by(event inst, event type) %>% summarize(
 n events=n().
 n miss inc = sum(is.na(med inc)),
 mean_inc=mean(med_inc, na.rm = TRUE),
 n_miss_frlunch = sum(is.na(fr_lunch)),
 mean fr lunch=mean(fr lunch, na.rm = TRUE))
```

#### Student exercise

- Using the event\_berk object, group by instnm, event\_inst, & event\_type.
  - 1.1 Create vars for number non\_missing for these racial/ethnic groups ( pct\_white\_zip , pct\_black\_zip , pct\_asian\_zip , pct\_hispanic\_zip , pct\_amerindian\_zip , pct\_nativehawaii\_zip )
  - 1.2 Create vars for mean percent for each racial/ethnic group

## Student exercise solutions

```
event_berk %>% group_by(instnm, event_inst, event_type) %>%
 summarize(
 n events=n().
 n_miss_white = sum(!is.na(pct_white_zip)),
 mean_white = mean(pct_white_zip, na.rm = TRUE),
 n_miss_black = sum(!is.na(pct_black_zip)),
 mean_black = mean(pct_black_zip, na.rm = TRUE),
 n_miss_asian = sum(!is.na(pct_asian_zip)),
 mean_asian = mean(pct_asian_zip, na.rm = TRUE),
 n_miss_lat = sum(!is.na(pct_hispanic_zip)),
 mean_lat = mean(pct_hispanic_zip, na.rm = TRUE),
 n_miss_na = sum(!is.na(pct_amerindian_zip)),
 mean_na = mean(pct_amerindian_zip, na.rm = TRUE),
 n_miss_nh = sum(!is.na(pct_nativehawaii_zip)),
 mean_nh = mean(pct_nativehawaii_zip, na.rm = TRUE)) %>%
 head(6)

                                                            89.7
#> # ... with 10 more variables: n_miss_black <int>, mean_black <dbl>,
#> # n miss asian <int>. mean asian <dbl>. n miss lat <int>.
```

summarize() and logical vectors, part II

## summarize() : counts with logical vectors, part II

Logical vectors (e.g., is.na() ) useful for counting obs that satisfy some condition

```
is.na(c(5,NA,4,NA))
#> [1] FALSE TRUE FALSE TRUE
typeof(is.na(c(5,NA,4,NA)))
#> [1] "logical"
sum(is.na(c(5,NA,4,NA)))
#> [1] 2
```

**Task**: Using object event\_berk , calculate the following measures for each combination of event\_type and event\_inst :

- count of number of rows for each group
- count of rows non-missing for both pct\_black\_zip and pct\_hispanic\_zip
- count of number of visits to communities where the sum of Black and Latinx people comprise more than 50% of the total population

```
event_berk %>% group_by (event_inst, event_type) %>%
summarize(
    n_events=n(),
    n_nonmiss_latbl = sum(!is.na(pct_black_zip) & !is.na(pct_hispanic_zip)),
    n_majority_latbl= sum(pct_black_zip+ pct_hispanic_zip>50, na.rm = TRUE)
)
```

## summarize() : logical vectors to count proportions

```
Synatx: group_by(vars) %>% summarize(prop = mean(TRUE/FALSE condition))
```

**Task**: separately for in-state/out-of-state, what proportion of visits to public high schools are to communities with median income greater than \$100,000?

### Steps:

- 1. Filter public HS visits
- 2. group by in-state vs. out-of-state
- 3. Create measure

#### What if we forgot to put na.rm=TRUE in the above task?

**Task**: separately for in-state/out-of-state, what proportion of visits to public high schools are to communities with median income greater than \$100,000?

# summarize() : Other "helper" functions

Lots of other functions we can use within summarize()

Common functions to use with summarize():

Function	Description
n	count
n_distinct	count unique values
mean	mean
median	median
max	largest value
min	smallest value
sd	standard deviation
sum	sum of values
first	first value
last	last value
nth	nth value
any	condition true for at least one value

Note: These functions can also be used on their own or with <code>mutate()</code>

## summarize() : Other functions

Maximum value in a group

```
max(c(10,50,8))
#> [1] 50
```

**Task**: For each combination of in-state/out-of-state and event type, what is the maximum value of med\_inc?

```
event_berk %>% group_by(event_type, event_inst) %>%
 summarize(max_inc = max(med_inc)) # oops, we forgot to remove NAs!
#> # A tibble: 10 x 3
#> event type event inst max inc
#> <chr> <chr> <dbl>
#> 1 2yr college In-State NA
#> 2 2yr college Out-State 153070.
#> 3 4yr college In-State NA
#> 4 4yr college Out-State NA
\#> 5 other In-State NA
#> 6 other Out-State NA
#> 7 private hs In-State 250001
#> 8 private hs Out-State NA
#> 9 public hs In-State NA
#> 10 public hs Out-State 223556.
event_berk %>% group_by(event_type, event_inst) %>%
 summarize(max_inc = max(med_inc, na.rm = TRUE))
#> # A tibble: 10 x 3
#> event_type event inst max inc
```

## summarize() : Other functions

Isolate first/last/nth observation in a group

```
x <- c(10,15,20,25,30)
first(x)
last(x)
nth(x,1)
nth(x,3)
nth(x,10)</pre>
```

Task: after sorting object event\_berk by event\_type and
event\_datetime\_start , what is the value of event\_date for:

- first event for each event type?
- the last event for each event type?
- ▶ the 50th event for each event type?

```
event_berk %>% arrange(event_type, event_datetime_start) %>%
  group_by(event_type) %>%
  summarize(
    n_events = n(),
    date_first= first(event_date),
    date_last= last(event_date),
    date_50th= nth(event_date, 50)
)
```

#### Student exercise

Identify value of event\_date for the nth event in each by group

#### Specific task:

- ▶ arrange (i.e., sort) by event\_type and event\_datetme\_start , then group by event\_type , and then identify the value of event\_date for:
  - the first event in each by group ( event\_type )
  - the second event in each by group
  - the third event in each by group
  - the fourth event in each by group
  - the fifth event in each by group

#### Student exercise solution

```
event_berk %>% arrange(event_type, event_datetime_start) %>%
 group by(event type) %>%
 summarize(
   n = n().
   date 1st= first(event date),
   date_2nd= nth(event_date,2),
   date 3rd= nth(event date,3),
   date 4th= nth(event date,4),
   date_5th= nth(event_date,5))
#> # A tibble: 5 x 7
#> event type n events date 1st date 2nd date 3rd date 4th
#> <chr> <int> <date> <date> <date>
#> 1 2yr colle~ 112 2017-04-25 2017-09-05 2017-09-05 2017-09-06
#> 2 4yr colle~ 18 2017-04-30 2017-05-01 2017-05-06 2017-09-13
#> 3 other 138 2017-04-11 2017-04-23 2017-04-25 2017-04-29
#> 4 private hs 169 2017-04-23 2017-04-24 2017-04-29 2017-04-30
#> 5 public hs 442 2017-04-14 2017-04-24 2017-04-26 2017-04-27
#> # ... with 1 more variable: date 5th <date>
```

Summarize multiple columns

## What are "scoped" variants of a function?

"Scoped" variants of a function apply the function to a selection of variables.

#### Three kinds of scoped variants exist:

- 1. Verbs (i.e., functions) suffixed with \_all() apply an operation on all variables.
  - e.g.: summarize\_all(), mutate\_all()
- 2. Verbs suffixed with \_at() (e.g., summarize\_at() ) apply an operation on a subset of variables specified with quoting function vars().
  - ▶ This quoting function accepts helpers functions like starts\_with()
- Verbs suffixed with \_if() apply an operation on the subset of variables for which a predicate function returns TRUE.

## Arguments of scoped variants

- .tbl A tbl object (data frame)
  - .funs specifies which function(s) to perform (e.g., calculate mean)
  - Argument values: A function fun; a quosure style lambda ~ fun(.); or a list of either form (e.g., 'list(mean,min,max).
- .vars which variables to apply function to:
  - argument values: A list of columns generated by vars(), a character vector of column names, a numeric vector of column positions, or NULL.
- .predicate A predicate function to be applied to the columns or a logical vector. The variables for which .predicate is or returns TRUE are selected.
- Additional arguments for function calls in .funs , evaluated once w/ tidy dots support

## What are "scoped" variants of a function?

Why/when use "scoped" variants of a function

When you want to perform an operation on multiple variables without naming each individual variable

```
"verbs" (i.e., functions) from the dplyr package that have scoped variants _all() , _at() , and _if()
```

- mutate() and transmute() [see ?mutate\_all ]
- summarize() [see ?summarize\_all ]
- filter()
- group\_by()
- rename() and select()
- arrange()

# Scoped variants of summarize()

**Description**. The "scoped variants" of summarize() apply summarize() to multiple variables. Three variants:

- summarize\_all() affects every variable
- summarize\_at() affects variables selected with a character vector or vars()
- summarize\_if() affects variables selected with a predicate function

### Syntax

- summarize\_all(.tbl, .funs, ...)
- summarize\_at(.tbl, .vars, .funs, ...)
- summarize\_if(.tbl, .predicate, .funs, ...)

#### Arguments

- .tbl A tbl object (data frame)
- .funs specifies which function(s) to perform (e.g., calculate mean)
  - Argument values: A function fun; a quosure style lambda ~ fun(.); or a list of either
- .vars which variables to apply function to:

form (e.g., 'list(mean,min,max).

- argument values: A list of columns generated by vars(), a character vector of column names, a numeric vector of column positions, or NULL.
- .predicate A predicate function to be applied to the columns or a logical vector. The variables for which .predicate is or returns TRUE are selected.
- Additional arguments for the function calls in .funs .
  - These are evaluated only once, with tidy dots support.

# summarize\_all() affects every variable

Syntax: summarize\_all(.tbl, .funs, ...)

- ▶ .tbl A tbl object (data frame)
- .funs specifies which function(s) to perform. Argument values:
  - A function fun; a quosure style lambda ~ fun(.); a list (e.g., list(mean,min)
- Additional arguments for function calls in .funs . These are evaluated once

#### Task:

► For U. Pittsburgh (univ\_id = 215293) events at public and private high schools, caclulate the mean value of med\_inc and pct\_white\_zip for each combination of event\_type and event\_inst

```
df_event %>%
  filter(univ_id == 215293, event_type %in% c("private hs","public hs")) %>%
  select(event_type, event_inst,med_inc,pct_white_zip) %>%
  group_by(event_type,event_inst) %>%
  summarize_all(.funs = mean)
```

Try again, this time applying na.rm = TRUE

```
this is an example of a ... argument "for the function calls in .funs."

df_event %>%
filter(univ_id == 215293, event_type %in% c("private hs", "public hs")) %>%
```

select(event\_type, event\_inst,med\_inc,pct\_white\_zip) %>%
group by(event type,event inst) %>%

summarize all(.funs = mean, na.rm = TRUE)

57 / 68

```
summarize_all() affects every variable
Syntax: summarize_all(.tbl, .funs, ...)
```

- .tbl A tbl object (data frame)
- .funs specifies which function(s) to perform. Argument values:
  - A function fun; a quosure style lambda ~ fun(.); a list (e.g., list(mean,min)
- ... Additional arguments for function calls in .funs . These are evaluated once

#### Task:

For U. Pittsburgh (univ\_id = 215293) events at public and private high schools, caclulate **mean** and **standard deviation** of med\_inc and pct\_white\_zip for each combination of event\_type and event\_inst

```
df_event %>%
  filter(univ_id == 215293, event_type %in% c("private hs","public hs")) %>%
  select(event_type, event_inst,med_inc,pct_white_zip) %>%
  group_by(event_type,event_inst) %>%
  summarize_all(.funs = list(mean,sd), na.rm = TRUE)
```

Use this syntax to control variable name suffixes:

# summarize\_all() affects every variable

#### Task:

Same task as before, but now calculate mean, standard deviation, min, and max of med\_inc and pct\_white\_zip for each combination of event\_type and event inst

```
df event %>%
 filter(univ_id == 215293, event_type %in% c("private hs", "public hs")) %>%
 select(event_type, event_inst,med_inc,pct_white_zip) %>%
 group_by(event_type,event_inst) %>%
 summarize_all(.funs = list(avg = mean, std = sd, low = min, high = max),
   na.rm = TRUE)
#> # A tibble: 4 x 10
#> event_type event_inst med_inc_avg pct_white_zip_a~ med_inc_std
#> <chr> <chr> <dhl> <dhl> <dhl>
#> 1 private hs In-State 77115.
                                         78.9 36559.
#> 2 private hs Out-State 103915. 63.3 44220.
#> 3 public hs In-State 78408. 83.0 25841.
#> 4 public hs Out-State 114212. 67.5 39745.
#> # ... with 5 more variables: pct_white_zip_std <dbl>, med_inc_low <dbl>,
#> # pct white zip low <dbl>, med inc high <dbl>, pct white zip high <dbl>
```

```
• funs specifies which function(s) to perform. Argument values:
     A function fun; a quosure style lambda ~ fun(.); a list (e.g., list(mean,min)
Task: Calculate mean, number of obs, and number of non-missing obs for variables
 Functions you specify within .funs require different options (e.g., some require
    na.rm = TRUE but others don't take arguments)
 Within .funs argument, specify functions using "quosure style lambda"
     Syntax: .funs = list(~ func_name(., options), ~ func_name(., options))
df event %>%
  filter(univ_id == 215293, event_type %in% c("private hs", "public hs")) %>%
  select(event_type, event_inst,med_inc,pop_total) %>%
  group_by(event_type,event_inst) %>%
  summarize all(.funs = list(~ mean(., na.rm = TRUE), ~ n(), ~ sum(!is.na(.))))
Specify suffix of variable name
df event %>%
  filter(univ_id == 215293, event_type %in% c("private hs", "public hs")) %>%
  select(event_type, event_inst,med_inc,pop_total) %>%
  group_by(event_type,event_inst) %>%
  summarize_all(.funs = list(avg = ~ mean(., na.rm = TRUE), nrow = ~ n(),
    n_nonmiss = ~ sum(!is.na(.))))
                                                                                60 / 68
```

summarize all(), quosure style lambdas  $\sim$  func name(.)

Syntax: summarize\_all(.tbl, .funs, ...)

# summarize\_at() affects selected variables

Syntax: summarize\_at(.tbl, .vars, .funs, ...)

- .tbl A tbl object (data frame)
- .vars which variables to operate on. Argument values:
  - ▶ A list of columns generated by vars(), a character vector of column names, a numeric vector of column positions, or NULL.
- .funs specifies which function(s) to perform. Argument values:
  - ► A function fun; a quosure style lambda ~ fun(.); a list (e.g., list(mean,min)
- Additional arguments for function calls in .funs . These are evaluated once

Task: For U. Pittsburgh events at public and private high schools, caclulate mean,
min, and max of variables med\_inc and event\_date for each combination of
 event\_type and event\_inst

df\_event %>%
 filter(univ\_id == 215293, event\_type %in% c("private hs", "public hs")) %>%
 group\_by(event\_type, event\_inst) %>%

```
.funs = list(avg = mean, low = min, high = max), na.rm = TRUE)
```

Alternative:

summarize at(.vars = vars(med inc,event date),

## summarize\_if() affects variables that satisfy some condition

Useful if you want to apply functions to variables that are particular type or class

Syntax: summarize\_if(.predicate, .tbl, .vars, .funs, ...)

- .tbl A tbl object (data frame)
- predicate A predicate function to be applied to columns or a logical vector.

The variables for which .predicate is or returns TRUE are selected.

- funs specifies which function(s) to perform.
- ... Additional arguments for function calls in .funs .

**Task**: For events by U. Pittsburgh at public and private high schools, caclulate mean and standard deviation for **numeric variables** 

## Attach aggregate measures to your data frame

We can attach aggregate measures to a data frame by using group\_by without summarize()

What do I mean by "attaching aggregate measures to a data frame"?

 Calculate measures at the by\_group level, but attach them to original object rather than creating an object with one row for each by\_group

**Task**: Using event\_berk data frame, create (1) a measure of average income across all events and (2) a measure of average income for each event type

resulting object should have same number of observations as event\_berk

### Steps:

- create measure of avg. income across all events without using group\_by() or summarize() and assign as (new) object
- Using object from previous step, create measure of avg. income across by event type using group\_by() without summarize() and assign as new object

## Attach aggregate measures to your data frame

**Task**: Using event\_berk data frame, create (1) a measure of average income across all events and (2) a measure of average income for each event type

1. Create measure of average income across all events

```
event_berk_temp <- event_berk %>%
  arrange(event_date) %>% # sort by event_date (optional)
  select(event_date, event_type,med_inc) %>% # select vars to be retained (optional)
  mutate(avg_inc = mean(med_inc, na.rm=TRUE)) # create avg. inc measure

dim(event_berk_temp)
event_berk_temp %>% head(5)
```

2. Create measure of average income by event type

```
event_berk_temp <- event_berk_temp %>%
  group_by(event_type) %>% # grouping by event type
  mutate(avg_inc_type = mean(med_inc, na.rm=TRUE)) # create avg. inc measure

str(event_berk_temp)
event_berk_temp %>% head(5)
```

## Attach aggregate measures to your data frame

**Task**: Using event\_berk\_temp from previous question, create a measure that identifies whether med\_inc associated with the event is higher/lower than average income for all events of that type

#### Steps:

- 1. Create measure of average income for each event type [already done]
- 2. Create 0/1 indicator that identifies whether median income at event location is higher than average median income for events of that type

```
# average income at recruiting events across all universities
event_berk_tempv2 <- event_berk_temp %>%
  mutate(gt_avg_inc_type = med_inc > avg_inc_type) %>%
  select(-(avg_inc)) # drop avg_inc (optional)
event_berk_tempv2 # note how med_ic = NA are treated
```

Same as above, but this time create integer indicator rather than logical

```
event_berk_tempv2 <- event_berk_tempv2 %>%
  mutate(gt_avg_inc_type = as.integer(med_inc > avg_inc_type))
event_berk_tempv2 %>% head(4)
```

### Student exercise

Task: is pct\_white\_zip at a particular event higher or lower than the average pct\_white\_zip for that event\_type ?

- ▶ Note: all events attached to a particular zip\_code
- pct\_white\_zip : pct of people in that zip\_code who identify as white

#### Steps in task:

- Create measure of average pct white for each event\_type
- Compare whether pct\_white\_zip is higher or lower than this average

#### Student exercise solution

Task: is pct\_white\_zip at a particular event higher or lower than the average pct\_white\_zip for that event\_type?

```
event_berk_tempv3 <- event_berk %>%
 arrange(event date) %>% # sort by event date (optional)
 select(event_date, event_type, pct_white_zip) %>% #optional
 group_by(event_type) %>% # grouping by event type
 mutate(avg_pct_white = mean(pct_white_zip, na.rm=TRUE),
        gt_avg_pctwhite_type = as.integer(pct_white_zip > avg_pct_white))
event berk tempv3 %>% head(4)
#> # A tibble: 4 x 5
#> event_date event_type pct_white_zip avg_pct_white gt_avg_pctwhite_type
\#> < date> < chr>
                        <db1>
                                            <db1>
                                                                \langle int \rangle
